École Polytechnique Fédérale de Lausanne

April 26, 2016

Today

- Further introduction to BIOGEME
- Estimation of Binary Logit models

How does BIOGEME work?

BIOGEME - Data file

- File extension .dat
- First row contains column (variable) names.
- One observation per row.
- Each row must contain a choice indicator.
- Example with the Netherlands transportation mode choice data: choice between car and train.

BIOGEME - Data file

netherlands.dat

id	choice	rail_cost	rail_time	car_cost	car_time
1	0	40	2.5	5	1.167
2	0	35	2.016	9	1.517
3	0	24	2.017	11.5	1.966
4	0	7.8	1.75	8.333	2
5	0	28	2.034	5	1.267
...					
219	1	35	2.416	6.4	1.283
220	1	30	2.334	2.083	1.667
221	1	35.7	1.834	16.667	2.017
222	1	47	1.833	72	1.533
223	1	30	1.967	30	1.267

BIOGEME - Data file

netherlands.dat

222	1	47	1.833	72	1.533
223	1	30	1.967	30	1.267

Choice indicator, 0: car and 1: train

BIOGEME - Model file

- File extension .mod
- Must be consistent with data file.
- Contains deterministic utility specifications, model type etc.
- The model file contains different [Sections] describing different elements of the model specification.

BIOGEME - Model file

- How can we write the following deterministic utility functions in BIOGEME?

$$V_{\text{car}} = \text{ASC}_{\text{car}} + \beta_{\text{time}} \text{time}_{\text{car}} + \beta_{\text{cost}} \text{cost}_{\text{car}}$$

$$V_{\text{rail}} = \beta_{\text{time}} \text{time}_{\text{rail}} + \beta_{\text{cost}} \text{cost}_{\text{rail}}$$

BIOGEME - Model file

BIOGEME Version 1.8 [Sat Mar 7 14:36:56 CEST 2009]

Michel Bierlaire, EPFL

This file has automatically been generated.

09/23/10 12:08:00

Model:Multinomial Logit

Number of estimated parameters:3

Number of observations:228

Number of individuals:228

Null log-likelihood:-158.038

Cte log-likelihood:-148.347

Init log-likelihood:-158.038

Final log-likelihood:-123.133

Likelihood ratio test:69.809

Rho-square:0.221

Adjusted rho-square:0.202

Final gradient norm:+6.045e-004

Diagnostic:Convergence reached...

Iterations:7

Run time:00:00

Variance-covariance:from analytical hessian

Sample file:netherlands05.dat

Utility parameters

Name	Value	Std err	t-test	p-value	Robust Std err	Robust t-test	p-value

Coefficient estimates

Today

- Further introduction to BIOGEME
- **Estimation of Binary Logit models**

Binary Logit Case Study

- Dataset: mode choice in Netherlands
- Description available on the course webpage.

How to go through the Case Studies

- Download the files related to the case study from the course webpage.
- Go through the .mod files with the help of the descriptions.
- Run the .mod files with BIOGEME.
- Interpret the results and compare your interpretation with the one we have proposed.
- Develop other model specifications.

Course webpage

- <http://transp-or.epfl.ch/>
→ Teaching → Decision-aid methodologies in transportation → Laboratories
- BIOGEME software
(including documentation and utilities)
- For each Case Study:
 - Data files;
 - Model specification files;
 - Possible interpretation of results.

Today's plan

Group work

- gather in groups;
- generate .mod file (base);
- test an idea/ hypothesis.

Specifying models: Recommended steps

- Formulate a-priori hypothesis:
 - Expectations and intuition regarding the explanatory variables that appear to be significant for mode choice.
- Specify a minimal model:
 - Start simple;
 - Include the main factors affecting the mode choice of (rational) travelers;
 - This will be your starting point.
- Continue adding and testing variables that improve the initial model..

Evaluating models

The main indicators used to evaluate and compare the various models are summarised here:

- Informal tests:
 - *signs* and *relative magnitudes* of the parameters β values (under our a-priori expectations);
 - *trade-offs* among some attributes and ratios of pairs of parameters (e.g. reasonable value of time).
- Overall goodness of fit measure:
 - *adjusted rho-square* (likelihood ratio index): takes into account the different number of explanatory variables used in the models and normalizes for their effect → suitable to compare models with different number of independent variables. We check this value to have a first idea about which model might be better (among models of the same type), but it is not a statistical test.

Evaluating models (cont.)

- Statistical tests:

- *t-test values*: statistically significant explanatory variables are denoted by t-statistic values remarkably higher/ lower than ± 2 (for a 95% level of confidence);
- *final log-likelihood* for the full set of parameters: should be remarkably different from the ones in the naive approach (null log-likelihood and log-likelihood at constants); we ask for high values of likelihood ratio test $[-2(LL(0) - LL(\beta))]$ in order to have a model significantly different than the naive one.

- Test of entire models:

- *likelihood ratio test* $[-2(LL(\hat{\beta}_R) - LL(\hat{\beta}_U))]$: used to test the null hypothesis that two models are equivalent, under the requirement that the one is the restricted version of the other. The likelihood ratio test is X^2 distributed, with degrees of freedom equal to $K_U - K_R$ (where K the number of parameters of the unrestricted and restricted model, respectively).
