Markov Chain Monte Carlo Methods – p. 1/36

#### **Markov Chains**

Andrey Markov, 1856–1922, Russian mathematician.

Markov Chain Monte Carlo Methods - p. 2/36

Glossary:

- Stochastic process:  $X_t$ , t = 0, 1, ..., collection of r.v. with same support, or states space  $\{1, ..., i, ..., J\}$ .
- Markov process: (short memory)

$$\Pr(X_t = i | X_0, \dots, X_{t-1}) = \Pr(X_t = i | X_{t-1})$$

• Homogeneous Markov process:

 $\Pr(X_t = j | X_{t-1} = i) = \Pr(X_{t+k} = j | X_{t-1+k} = i) = P_{ij} \quad \forall t \ge 1, k \ge 0.$ 

- Transition matrix:  $P \in \mathbb{R}^{J \times J}$ .
- Properties:

$$\sum_{j=1}^{J} P_{ij} = 1, \ i = 1, \dots, J, \ P_{ij} \ge 0, \ \forall i, j,$$
  
Transp-or

Markov Chain Monte Carlo Methods - p. 3/36

# **Markov Chains**

- If state *j* can be reached from state *i* with non zero probability, we say that *i* communicates with *j*.
- Two states that communicate belong to the same *class*.
- A Markov chain is *irreducible* or *ergodic* if it contains only one class.
- With an ergodic chain, it is possible to go to every state from any state.

# **Markov Chains**

- $P_{ij}^t$  is the probability that the process reaches state *j* from *i* after *t* steps.
- Consider all t such that  $P_{ii}^t > 0$ . The largest common divisor d is called the *period* of state i.
- A state with period 1 is *aperiodic*.
- If  $P_{ii} > 0$ , state *i* is aperiodic.
- The period is the same for all states in the same class.
- Therefore, if the chain is irreducible, if one state is aperiodic, they all are.

#### A periodic chain

Markov Chain Monte Carlo Methods - p. 6/36

#### **Markov Chains**

$$\Pr(j) = \sum_{i=1}^{J} \Pr(j|i) \Pr(i)$$

• Stationary probabilities: unique solution of the system

$$\pi_j = \sum_{i=1}^{J} P_{ij} \pi_i, \quad \forall j = 1, \dots, J.$$
 (1)

$$\sum_{j=1}^{J} \pi_j = 1.$$

• Solution exists for any irreducible chain.

Markov Chain Monte Carlo Methods - p. 7/36

#### **Markov Chains**

• Consider the following system of equations:

$$x_i P_{ij} = x_j P_{ji}, \ i \neq j, \ \sum_{i=1}^J x_i = 1$$
 (2)

• We sum over *i*:

$$\sum_{i=1}^{J} x_i P_{ij} = x_j \sum_{i=1}^{J} P_{ji} = x_j.$$

• If (2) has a solution, it is also a solution of (1). As  $\pi$  is the unique solution of (1) then  $x = \pi$ .

$$\pi_i P_{ij} = \pi_j P_{ji}, \quad i \neq j$$

# Example

- A machine can be in 4 states with respect to wear
  - perfect condition,
  - partially damaged,
  - seriously damaged,
  - completely useless.
- The degradation process can be modeled by an irreducible aperiodic homogeneous Markov process, with the following transition matrix:

$$P = \left(\begin{array}{cccccccc} 0.95 & 0.04 & 0.01 & 0.0 \\ 0.0 & 0.90 & 0.05 & 0.05 \\ 0.0 & 0.0 & 0.80 & 0.20 \\ 1.0 & 0.0 & 0.0 & 0.0 \end{array}\right)$$

# Example

Stationary distribution:  $\left(\frac{5}{8}, \frac{1}{4}, \frac{3}{32}, \frac{1}{32}\right)$ 

$$\left(\frac{5}{8}, \frac{1}{4}, \frac{3}{32}, \frac{1}{32}\right) \left(\begin{array}{cccc} 0.95 & 0.04 & 0.01 & 0.0\\ 0.0 & 0.90 & 0.05 & 0.05\\ 0.0 & 0.0 & 0.80 & 0.20\\ 1.0 & 0.0 & 0.0 & 0.0 \end{array}\right) = \left(\frac{5}{8}, \frac{1}{4}, \frac{3}{32}, \frac{1}{32}\right)$$

- Machine in perfect condition 5 days out of 8, in average.
- Repair occurs in average every 32 days

From now on: Markov process = irreducible aperiodic homogeneous Markov process

# **Stationary distributions**

• Property:

$$\pi_j = \lim_{t \to \infty} \Pr(X_t = j) \ j = 1, \dots, J.$$

- Ergodicity:
  - Let *f* be any function on the state space.
  - Then, with probability 1,

$$\lim_{T \to \infty} \frac{1}{T} \sum_{t=1}^{T} f(X_t) = \sum_{j=1}^{J} \pi_j f(j).$$

• Computing the expectation of a function of the stationary states is the same as to take the average of the values along a trajectory of the process.

#### Simulation

• We want to simulate a r.v. X with pmf

$$\Pr(X=j) = p_j.$$

- We generate a Markov process with limiting probabilities  $p_j$  (how?)
- We simulate the evolution of the process.

$$p_j = \pi_j = \lim_{t \to \infty} \Pr(X_t = j) \ j = 1, \dots, J.$$

#### **Example:** T = 100

Markov Chain Monte Carlo Methods – p. 13/36

#### **Example:** T = 1000

Markov Chain Monte Carlo Methods - p. 14/36

#### **Example:** T = 10000

Markov Chain Monte Carlo Methods - p. 15/36

#### Simulation

• Assume that we are interested in simulating

$$\operatorname{E}[f(X)] = \sum_{j=1}^{J} f(j)p_j.$$

• We use ergodicity to estimate it with

$$\frac{1}{T}\sum_{t=1}^{T}f(X_t).$$

• We should drop early states (see above example). Better estimate:

$$\frac{1}{T}\sum_{t=1+k}^{T+k} f(X_t).$$

Nicholas Metropolis 1915 – 1999 W. Keith Hastings 1930 –

- Let  $b_j$ ,  $j = 1, \ldots, J$  be positive numbers.
- Let  $B = \sum_j b_j$ .
- Let  $\pi_j = b_j/B$ .
- We want to simulate a r.v. with pmf  $\pi_j$ .
- Consider a Markov process on  $\{1, \ldots, J\}$  with transition probability Q.
- Define another Markov process with the same states in the following way:
  - Assume the process is in state *i*, that is  $X_t = i$ ,
  - Simulate the (candidate) next state *j* according to *Q*.
  - Define

$$X_{t+1} = \left\{ egin{array}{cc} j & {
m with \ probability \ lpha_{ij}} \ i & {
m with \ probability \ 1-lpha_{ij}} \end{array} 
ight.$$

• Transition probability *P*:

$$P_{ij} = Q_{ij}\alpha_{ij} \qquad \text{if } i \neq j$$
  

$$P_{ii} = Q_{ii}\alpha_{ii} + \sum_{\ell \neq i} Q_{i\ell}(1 - \alpha_{i\ell}) \quad \text{otherwise}$$

• Must verify the property:

$$1 = \sum_{j} P_{ij} = P_{ii} + \sum_{j \neq i} P_{ij}$$
  
=  $Q_{ii} \alpha_{ii} + \sum_{\ell \neq i} Q_{i\ell} (1 - \alpha_{i\ell}) + \sum_{j \neq i} Q_{ij} \alpha_{ij}$   
=  $Q_{ii} \alpha_{ii} + \sum_{\ell \neq i} Q_{i\ell} - \sum_{\ell \neq i} Q_{i\ell} \alpha_{i\ell} + \sum_{j \neq i} Q_{ij} \alpha_{ij}$   
=  $Q_{ii} \alpha_{ii} + \sum_{\ell \neq i} Q_{i\ell}$ 

As 
$$\sum_{j} Q_{ij} = 1$$
, we have  $\alpha_{ii} = 1$ .

• Stationary distribution and time reversibility:

$$\pi_i P_{ij} = \pi_j P_{ji}, \quad i \neq j$$

• that is

$$\pi_i Q_{ij} \alpha_{ij} = \pi_j Q_{ji} \alpha_{ji}, \quad i \neq j$$

• It is satisfied if

$$\alpha_{ij} = \frac{\pi_j Q_{ji}}{\pi_i Q_{ij}} \text{ and } \alpha_{ji} = 1$$

or

$$\frac{\pi_i Q_{ij}}{\pi_j Q_{ji}} = \alpha_{ji} \text{ and } \alpha_{ij} = 1$$

• Therefore

$$\alpha_{ij} = \min\left(\frac{\pi_j Q_{ji}}{\pi_i Q_{ij}}, 1\right)$$

• Remember:  $\pi_j = b_j/B$ . Therefore

$$\alpha_{ij} = \min\left(\frac{b_j BQ_{ji}}{b_i BQ_{ij}}, 1\right) = \min\left(\frac{b_j Q_{ji}}{b_i Q_{ij}}, 1\right)$$

- The normalization constant *B* does not play a role in the computation of  $\alpha_{ij}$ .
- In summary:
  - Given Q and  $b_j$
  - defining  $\alpha$  as above
  - creates a Markov process characterized by P
  - with stationary distribution  $\pi$ .

Algorithm:

- 1. Choose a Markov process characterized by  $\boldsymbol{Q}.$
- 2. Initialize the chain with a state  $i\colon \quad t=0\,,$   $X_0=i\,.$
- 3. Simulate the (candidate) next state  $\boldsymbol{j}$  based on  $\boldsymbol{Q}.$
- 4. Let r be a draw from  $U[0,1[\,.$

5. Compare 
$$r$$
 with  $\alpha_{ij} = \min\left(\frac{b_j Q_{ji}}{b_i Q_{ij}}, 1\right)$ . If

$$r < \frac{b_j Q_{ji}}{b_i Q_{ij}}$$

then  $X_{t+1} = j$ , else  $X_{t+1} = i$ .

- 6. Increase t by one.
- 7. Sto step 3. TRANSP-DR

#### Example

$$b = (20, 8, 3, 1)$$

$$\pi = \left(\frac{5}{8}, \frac{1}{4}, \frac{3}{32}, \frac{1}{32}\right)$$

$$Q = \left(\begin{array}{cccc} \frac{1}{4} & \frac{1}{4}, \frac{1}{4}, \frac{1}{32}, \frac{1}{32}\\ \frac{1}{4} & \frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4}\\ \frac{1}{4} & \frac{1}{4}\\ \frac{1}{4}\\ \frac{1}{4} &$$

Run MH for 10000 iterations. Collect statistics after 1000.

- Accept: [2488, 1532, 801, 283]
- Reject: [0, 952, 1705, 2239]
- Simulated: [0.627, 0.250, 0.095, 0.028]
- Target: [0.625, 0.250, 0.09375, 0.03125]

## **Gibbs sampling**

- Let  $X = (X^1, X^2, \dots, X^n)$  be a random vector with pmf (or pdf) p(x).
- Assume we can draw from the marginals:

$$\Pr(X^{i}|X^{j} = x^{j}, j \neq i), i = 1, ..., n.$$

- Markov process. Assume current state is *x*.
  - Draw randomly (equal probability) a coordinate *i*.
  - Draw r from the ith marginal.
  - New state:  $y = (x^1, ..., x^{i-1}, r, x^{i+1}, ..., x^n)$ .

# **Gibbs sampling**

• Transition probability:

$$Q_{xy} = \frac{1}{n} \Pr(X^i = r | X^j = x^j, \ j \neq i) = \frac{p(y)}{n \Pr(X^j = x^j, \ j \neq i)}$$

- The denominator is independent of  $X_i$ .
- So  $Q_{xy}$  is proportional to p(y).
- Metropolis-Hastings:

$$\alpha_{xy} = \min\left(\frac{p(y)Q_{yx}}{p(x)Q_{xy}}, 1\right) = \min\left(\frac{p(y)p(x)}{p(x)p(y)}, 1\right) = 1$$

• The candidate state is always accepted.

# **Example: bivariate normal distribution**

$$\begin{pmatrix} X \\ Y \end{pmatrix} \sim N\left( \begin{pmatrix} \mu_X \\ \mu_Y \end{pmatrix}, \begin{pmatrix} \sigma_X^2 & \rho\sigma_X\sigma_Y \\ \rho\sigma_X\sigma_Y & \sigma_Y^2 \end{pmatrix} \right)$$

Marginal distribution:

$$Y|(X=x) \sim N\left(\mu_Y + \frac{\sigma_Y}{\sigma_X}\rho(x-\mu_X), (1-\rho^2)\sigma_Y^2\right)$$

Apply Gibbs sampling to draw from:

$$N\left(\left(\begin{array}{c}0\\0\end{array}\right), \left(\begin{array}{c}1&0.9\\0.9&1\end{array}\right)\right)$$

Note: just for illustration. Should use Cholesky factor.

Markov Chain Monte Carlo Methods – p. 26/36

Markov Chain Monte Carlo Methods - p. 27/36

## **Example: draws from Gibbs sampling**

Markov Chain Monte Carlo Methods - p. 28/36

# Simulated annealing

- Application of the Metropolis-Hastings algorithm to optimization.
- Name comes from analogy with annealing in metallurgy, involving heating and controlled cooling of a material to reduce its defects.
- Optimization problem:

 $\min_{x \in \mathcal{F}} f(x)$ 

where the feasible set  $\mathcal{F}$  is a finite set of vectors.

• Let  $\mathcal{X}^*$  be the set of optimal solutions, that is

 $\mathcal{X}^* = \{ x \in \mathcal{F} | f(x) \leq f(y), \ \forall y \in \mathcal{F} \} \text{ and } f(x^*) = f^*, \ \forall x^* \in \mathcal{X}^*.$ 

- Consider the pmf on  ${\mathcal F}$ 

$$p_{\lambda}(x) = \frac{e^{-\lambda f(x)}}{\sum_{y \in \mathcal{F}} e^{-\lambda f(y)}}, \ \lambda > 0.$$

## **Simulated annealing**

$$p_{\lambda}(x) = \frac{e^{-\lambda f(x)}}{\sum_{y \in \mathcal{F}} e^{-\lambda f(y)}}$$

• Equivalently

$$p_{\lambda}(x) = \frac{e^{\lambda(f^* - f(x))}}{\sum_{y \in \mathcal{F}} e^{\lambda(f^* - f(y))}}$$

- As  $f^* - f(x) \leq 0$ , when  $\lambda \to \infty$ , we have

$$\lim_{\lambda \to \infty} p_{\lambda}(x) = \frac{\delta(x \in \mathcal{X}^*)}{|\mathcal{X}^*|},$$

where

$$\delta(x \in \mathcal{X}^*) = \begin{cases} 1 & \text{if } x \in \mathcal{X}^* \\ 0 & \text{otherwise.} \end{cases}$$

Example

$$\mathcal{F} = \{1, 2, 3\} f(\mathcal{F}) = \{0, 1, 0\}$$
$$p_{\lambda}(1) = \frac{1}{2 + e^{-\lambda}}$$
$$p_{\lambda}(2) = \frac{e^{-\lambda}}{2 + e^{-\lambda}}$$
$$p_{\lambda}(3) = \frac{1}{2 + e^{-\lambda}}$$

Markov Chain Monte Carlo Methods - p. 31/36

#### Example

Markov Chain Monte Carlo Methods - p. 32/36

# Simulated annealing

- If  $\lambda$  is large,
- we generate a Markov chain with stationary distribution  $p_{\lambda}(x)$ .
- The mass is concentrated on optimal solutions.
- As the normalizing constant is not needed, only  $e^{\lambda(f^* f(x))}$  is used.
- Construction of the Markov process through the concept of *neighborhood*.
- A *neighbor* y of x is obtained by simple modifications of x.
- The Markov process will proceed from neighbors to neighbors.
- The neighborhood structure must be designed such that the chain is irreducible, that is the whole space  $\mathcal{F}$  must be covered.
- It must be designed also such that the size of the neighborhood is reasonably small.

# Neighborhood

- Examples of neighborhoods:
  - x and y are neighbors if they differ only in one coordinate.
  - x and y are neighbors if two elements are interchanged.
- Denote N(x) the set of neighbors of x.
- Define a Markov process where the next state is a randomly drawn neighbor.
- Transition probability:

$$Q_{xy} = \frac{1}{|N(x)|}$$

• Metropolis Hastings:

$$\alpha_{xy} = \min\left(\frac{p(y)Q_{yx}}{p(x)Q_{xy}}, 1\right) = \min\left(\frac{e^{-\lambda f(y)}|N(x)|}{e^{-\lambda f(x)}|N(y)|}, 1\right)$$
  
Ransp-or

#### Notes

• The neighborhood structure can always be arranged so that each vector has the same number of neighbors. In this case,

$$\alpha_{xy} = \min\left(\frac{e^{-\lambda f(y)}}{e^{-\lambda f(x)}}, 1\right)$$

- If *y* is better than *x*, the next state is automatically accepted.
- Otherwise, it is accepted with a probability that depends on  $\lambda$ .
- If  $\lambda$  is high, the probability is small.
- When  $\lambda$  is small, it is easy to escape from local optima.

#### Notes

- In practice, it may be better to enumerate  $\mathcal{F}$  (MH is asymptotic while  $\mathcal{F}$  is finite).
- It is therefore usually used as a heuristic, where the value of  $\lambda$  is changed over time. For instance

 $\lambda_k = C \ln(1+k), \ C > 0.$ 

• The heuristic returns the best solution encountered during the process.
