Choice model as an optimization problem

Travel demand: activity based models

Combinatorial choices

Prediction

Estimation

Predicting choice behavior

Decision rule

Homo economicus

Rational and narrowly self-interested economic actor who is optimizing her outcome

Behavioral assumptions

- ▶ The decision maker solves an optimization problem.
- ► The analyst needs to define
 - the decision variables,
 - the objective function,
 - the constraints.

Continuous case: classical microeconomics

Optimization problem

$$\max_{q} \widetilde{U}(q; \theta)$$

subject to

$$p^T q \leqslant I, \ q \geqslant 0.$$

Demand function

- Solution of the optimization problem.
- KKT optimality conditions:

$$q^* = f(I, p; \theta)$$

Discrete choices

How does it work for discrete choices?

Utility maximization

Optimization problem

$$\max_{q,w} \widetilde{U}(q,w;\theta)$$

subject to

$$\begin{aligned} p^T q + c^T w &\leqslant I \\ \sum_j w_j &= 1 \\ w_j &\in \{0, 1\}, \forall j. \end{aligned}$$

where $c^T = (c_1, \ldots, c_j, \ldots, c_J)$ contains the cost of each alternative.

Derivation of demand functions

- Mixed integer optimization problem
- No optimality condition
- Impossible to derive demand functions directly

Derivation of the demand functions

Step 1: condition on the choice of the discrete good

- ightharpoonup Fix the discrete good(s), that is select a feasible w.
- Derive the <u>conditional</u> demand functions from KKT.

Step 2: enumerate all alternatives

- Enumerate all alternatives.
- ightharpoonup Compute the conditional indirect utility function U_i .
- ▶ Select the alternative with the highest U_i .

Enumerate all alternatives ??????

Starbucks has 383 billion unique latte combinations, [Merritt, 2023]

Activity-based models

- Activity participation
- Activity type
- Activity location
- Activity timing
- Activity duration
- Activity scheduling
- Activity frequency
- Travel mode choice
- Route choice
- ► Departure time choice

- ► Trip chaining / Tour formation
- ► Vehicle usage
- ► Parking choice
- Joint activity participation
- ► Ride-sharing / Carpooling decision
- Household resource allocation
- Teleworking decision
- ► Trip cancellation or rescheduling
- Use of on-demand mobility services
- ... and many more

Outline

Choice model as an optimization problem

Travel demand: activity based models

Combinatorial choices

Prediction

Estimation

Activities

Why do people travel?

- ▶ Most of the time, not for the sake of it.
- Activities.
- Spread in space and time.

Activity-based models: literature

Econometric models

- Discrete choice models.
- Curse of dimensionality.
- Decomposition: sequence of choices
 - Activity pattern
 - Primary tour: time of day
 - Primary tour: destination and mode
 - Secondary tour: time of day
 - Secondary tour: destination and mode
 - e.g. [Bowman and Ben-Akiva, 2001]

Rule-based models

- ► If the selected activity is at location *L*,
- ▶ and the travel time from current location C to L exceeds T_{max} ,
- then reject the activity-location combination,
- unless it is a high-utility or infrequent activity (e.g., doctor appointment).
- e.g. [Arentze et al., 2000]

Research question: can we combine the two?

	Econometric	Rule-based

Parameters inference	X	_
Testing/validation	X	
Joint decisions		X
Complex rules		X
Complex constraints	_	X

Outline

Choice model as an optimization problem

Travel demand: activity based models

Combinatorial choices

Prediction

Estimation

Combinatorial choices

Mathematical optimization

- Each individual is solving a combinatorial optimization problem.
- ▶ Decisions: see the long list before...
- ▶ Objective function: utility (to be maximized).
- Constraints: complex rules.

Example: activity schedule

The context

- Given a list of potential activities,
- with preferred starting time and duration,
- identify a feasible schedule,
- that maximizes utility.

Example: activity schedule

Decision variables

- ► Activity participation: $\phi_a \in \{0, 1\}$,
- ▶ Activity scheduling: $\phi_{ab} \in \{0, 1\}$,
- ▶ Activity start time: $s_a \in \mathbb{R}$,
- Activity duration: $\tau_a \in \mathbb{R}$,

Schedule utility

$$U_S = \sum_{a=0}^{A} \Phi_a (U_a^{ ext{participation}} + U_a^{ ext{start time}} + U_a^{ ext{duration}} + \sum_{b=0}^{A} \Phi_{ab} U_{a,b}^{ ext{travel}})$$

Example: utility schedule

Utility components

$$\textit{U}_{\textit{a}}^{\text{duration}} = \theta_{\textit{a}}^{\text{short}} \max(\textbf{0}, \tau_{\textit{a}}^* - \tau_{\textit{a}}) + \theta_{\textit{a}}^{\text{long}} \max(\textbf{0}, \tau_{\textit{a}} - \tau_{\textit{a}}^*) + \xi_{\text{duration}}$$

$$U_{a}^{\rm starting} = \theta_{a}^{\rm early} \max(\textbf{0}, s_{a}^* - s_{a}) + \theta_{a}^{\rm late} \max(\textbf{0}, s_{a} - s_{a}^*) + \xi_{\rm starting}$$

Example: utility schedule

Constraints

$$T=24\mathrm{h},$$

$$\sum_{a} \varphi_{a} \tau_{a} = T,$$

$$x_{b} \geqslant x_{a} + \tau_{a} + d_{ab} - T(1-\varphi_{ab}) \qquad \forall a,b,$$

$$x_{b} \leqslant x_{a} + \tau_{a} + d_{ab} + T(1-\varphi_{ab}) \qquad \forall a,b,$$

and many others...

Combinatorial choice model

Decision variables

$$\varphi \in \{0, 1\}^K$$

Total: 2^K combinations.

Choice set: defined by constraints

$$\mathcal{C}_n = \{ \varphi \mid g_n(\varphi) \leqslant 0, h_n(\varphi) = 0 \}.$$

Combinatorial choice model

Utility

$$U_{\phi,n} = V_n(\phi, x_n, \xi_n; \theta) + \nu_{\phi,n},$$

where

- $\triangleright \nu_{\Phi,n}$ are i.i.d. extreme value,
- \triangleright ξ_n is a random vector, capturing
 - correlation among alternatives,
 - taste heterogeneity,
 - etc.
- \triangleright θ is a vector of unknown parameters, to be estimated from data.

Combinatorial choice model

Mixture of logit models

$$P_n(\phi|x_n, \xi_n; \theta) = \frac{e^{U_{\phi,n}}}{\sum_{\ell \in \mathcal{C}_n} e^{U_{\ell,n}}},$$

$$P_n(\phi|x_n; \theta) = \int_{\xi} P_n(\phi|x_n, \xi_n; \theta) d\xi.$$

Main challenge

- ▶ Enumeration of \mathcal{C}_n is impossible.
- ► Calculating the probability is impossible.

Challenges

Your mission, should you choose to accept it

- Use the model for prediction.
- ☐ Estimate its parameters from data.

Outline

Choice model as an optimization problem

Travel demand: activity based models

Combinatorial choices

Prediction

Estimation

Use the model

Idea

- We cannot calculate the probability.
- ▶ But we do not really need it, do we?
- ▶ In order to identify the chosen alternative, we rely on simulation.
- ► Actually, simulation would be necessary anyway for the integral.

Methodology

- ▶ Draw independent realizations ξ_{nr} of ξ_n .
- Draw the chosen alternative from the logit model

$$\pi(\phi) = P_n(\phi|x_n, \xi_{nr}; \theta).$$

lacktriangle Metropolis-Hastings uses only the numerator $e^{U_{\Phi,n}}$.

Metropolis-Hastings: general idea

Goal

- ▶ We want to generate draws from a complicated target distribution $\pi(\cdot)$.
- Direct sampling is impossible.
- Metropolis–Hastings constructs a Markov chain whose stationary distribution is $\pi(\cdot)$.
- Markov chain Monte-Carlo method.

Algorithm ingredients

- ► Target distribution: $\pi(\phi) \propto e^{U_{\phi,n}}$.
- ▶ Proposal distribution: $q(\phi'|\phi)$, easy to sample from.

Metropolis-Hastings: Steps

Iteration $t \rightarrow t+1$

- ightharpoonup Current state: $\Phi^{(t)}$.
- ▶ **Step 1.** Draw a candidate ϕ' from $q(\cdot|\phi^{(t)})$.
- ▶ **Step 2.** Compute the acceptance probability

$$\alpha = \min \left(1, \frac{\pi(\varphi') \, q(\varphi^{(t)}|\varphi')}{\pi(\varphi^{(t)}) \, q(\varphi'|\varphi^{(t)})} \right) = \min \left(1, \frac{e^{U_{\varphi',n}} \, q(\varphi^{(t)}|\varphi')}{e^{U_{\varphi^{(t),n}}} \, q(\varphi'|\varphi^{(t)})} \right).$$

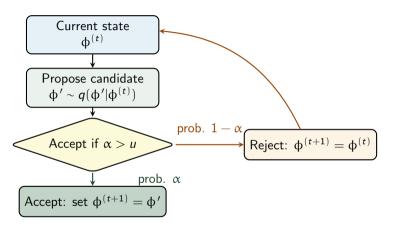

▶ **Step 3.** With probability α , accept and set $\phi^{(t+1)} = \phi'$. Otherwise, reject and keep $\phi^{(t+1)} = \phi^{(t)}$.

Key property

- ▶ The chain has stationary distribution $\pi(\cdot)$.
- Here, $\pi(\Phi) \propto e^{U_{\Phi,n}}$, so only the numerator of the logit formula is needed.

28 / 46

Metropolis-Hastings: Illustration

Acceptance probability:
$$\alpha = \min \left(1, \frac{e^{U_{\varphi',n}} \, q(\varphi^{(t)}|\varphi')}{e^{U_{\varphi^{(t)},n}} \, q(\varphi'|\varphi^{(t)})} \right).$$

Metropolis-Hastings

Is it magic?

- ▶ Key to success: well-designed proposal distribution $q(\cdot)$.
- ► Smart exploration of the choice set.
- Must exploit its structure to generate high probability alternatives.

Optimization-based choice problem

- By design, an optimization approach generates "good" alternatives.
- Main challenge: ergodicity.
- ▶ It means that the Markov chain must potentially cover the whole choice set.

[Flötteröd and Bierlaire, 2013], [Pougala et al., 2023]

Challenges

Your mission, should you choose to accept it

- ✓ Use the model for prediction.
- ☐ Estimate its parameters from data.

Outline

Choice model as an optimization problem

Travel demand: activity based models

Combinatorial choices

Prediction

Estimation

Parameters inference

Research question

- ▶ Given the values of the parameters, we can simulate the chosen alternative.
- What about the opposite?
- \triangleright Given observed choices, we want to infer the value of the parameters θ .

Sampling of alternatives

[McFadden, 1978]

- ightharpoonup Assign to each observation n a subset D_n of alternatives.
- \blacktriangleright $\pi_n(D|i)$ the probability to generate subset D, when i is observed.
- Contribution to the likelihood of observation *n*:

$$\pi_n(i|D) = \frac{\pi_n(D|i)P_n(i)}{\sum_{j \in D} \pi_n(D|j)P_n(j)}$$
 [Bayes]

For logit

$$\pi_n(i|D) = \frac{e^{V_{in} + \ln \pi_n(D|i)}}{\sum_{i \in D} e^{V_{jn} + \ln \pi_n(D|j)}}.$$

- ▶ No more sum over \mathcal{C}_n .
- It works also for Bayesian estimation [Dekker et al., 2025].

Proposed sampling protocol

Sample only one more alternative

- \triangleright ϕ_n is the chosen alternative for observation n.
- ightharpoonup θ_{cand} is a candidate for the parameters.
- Use simulation to generate a "chosen" alternative φ_n , conditional on θ_{cand} .
- Define

$$D_n = \{ \phi_n, \varphi_n \}.$$

Comments

- ▶ If $\varphi_n = \varphi_n$, D_n contains only one alternative, extremely rare when \mathcal{C}_n is huge,
- ▶ Intuition: a single good competitor is sufficient to identify the trade-offs.
- Contribution to the likelihood of each observation: binary logit model.

Bayesian estimation

Traditional Bayesian estimation

Use MH to draw from the posterior = likelihood \times prior (up to normalization):

$$p(\theta \mid \mathsf{data}) \propto p(\mathsf{data} \mid \theta) \, p(\theta)$$

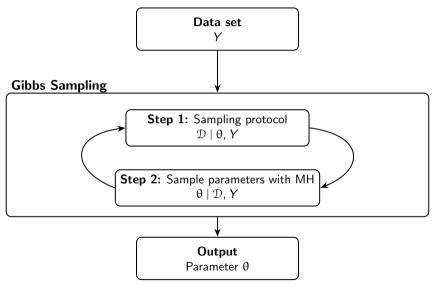

Proposed Bayesian estimation

Use Gibbs sampling to draw from $p(\theta, D \mid data)$:

- 1. Apply sampling protocol to draw from $p(D \mid \theta, data)$.
- 2. Use MH to draw from

$$p(\theta \mid D, \mathsf{data}) \propto p(\mathsf{data} \mid D, \theta) p(\theta).$$

Bayesian estimation

Case study

Restaurant choice model

- ➤ Synthetic dataset similar to [Bierlaire and Paschalidis, 2023] and [Bierlaire and Krueger, 2024]
- ▶ Full choice set \mathcal{C} : J = 100 restaurants
- \triangleright $N=10^4$ individuals
- Observed choices generated synthetically with a logit model

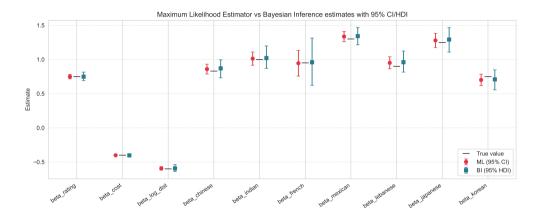

$$V_{jn} = \theta_{\mathsf{cost}} \, \mathsf{price}_j + \theta_{\mathsf{rate}} \, \mathsf{rating}_j + \theta_{\log d} \, \log(\mathsf{dist}_{jn}) + \sum_{c \in \mathcal{C}_{\mathsf{cuisine}}} \theta_c \, \mathbb{1}\{j \, \, \mathsf{is \, cuisine} \, \, c\}$$

Comparison of Estimation Methods

	MLE (Biogeme)	Bayesian Inference (PyMC)
Method	Maximum Likelihood Estimation	Gibbs Sampling $+$ MH
Solver	BFGS (with simple bounds)	Metropolis–Hastings
Convergence	86 iterations	12000 draws
Solver time	5 min 12 s	73 s
Full run time	7 min 18 s	2 min 38 s

MLE estimates parameters using the full choice set, while the Bayesian sampler compares only the chosen alternative with one sampled competitor (binary logit submodel).

Comparison between MLE and BI

Bayesian inference gives similar results looking only at 2 alternatives at a time.

Summary

- Large scale choice models.
- Numerical solution of the utility maximization problem.
- Impossibility to enumerate alternatives in the choice set.
- Main idea: rely on Markov chain Monte-Carlo methods, both for prediction and estimation.
- First results are particularly encouraging.

Challenges

Your mission, should you choose to accept it

- Use the model for prediction.
- Estimate its parameters from data.

This presentation will self-destruct in 5 seconds.
