# A multi-objective approach for station clustering in bike sharing systems

#### Selin Ataç, Nikola Obrenović, Michel Bierlaire

Transport and Mobility Laboratory School of Architecture, Civil and Environmental Engineering École Polytechnique Fédérale de Lausanne

September 14, 2021

#### Outline

- 1. Introduction
  - Previous work
  - Literature
- 2. Methodology
  - Clustering
- 3. Computational experiments
  - Case studies
  - Experiments
  - Results
- 4. Conclusion

ELE NOR

#### Introduction

• 14 % of the global greenhouse gas emissions is due to transportation (Pachauri et al., 2014).

-

#### Introduction

- 14 % of the global greenhouse gas emissions is due to transportation (Pachauri et al., 2014).
- More sustainable solutions
  - Carbon neutral fuel and electric cars
  - Ride-sharing and vehicle sharing (car, bike, e-scooter, etc.)

#### Introduction

- 14 % of the global greenhouse gas emissions is due to transportation (Pachauri et al., 2014).
- More sustainable solutions
  - Carbon neutral fuel and electric cars
  - Ride-sharing and vehicle sharing (car, bike, e-scooter, etc.)
- Bike sharing systems (BSSs)
  - Short rentals
  - Higher bike and less parking utilization
  - Examples: PubliBike, nextbike, mobike

It comes with operational challenges.

• In Ataç et al. (2020), we look into the relationship between rebalancing operations and demand forecasting.

EL OQO

It comes with operational challenges.

• In Ataç et al. (2020), we look into the relationship between rebalancing operations and demand forecasting.

Real world

Discrete event simulations to imitate the daily demand

Modeling flexible and stochastic system behavior

Decision center

Mathematical models to determine the routing of rebalancing operations

More specific and sometimes unrealistic decisions

Two cases are investigated:

- Unknown demand: we rebalance the system to the same initial state every day.
- Known demand: we assume that we perfectly know the trip demand of the following day. The initial state of the next day is determined by considering the pick-up and drop-offs at a station throughout the time horizon of the following day.

The main idea is to see how the cost of rebalancing operations and the number of lost demand differ between the two cases, and thereby evaluate the demand forecasting by analyzing the trade-off between the two scenarios.

DOC SE VEN

Two cases are investigated:

- Unknown demand: we rebalance the system to the same initial state every day.
- Known demand: we assume that we perfectly know the trip demand of the following day. The initial state of the next day is determined by considering the pick-up and drop-offs at a station throughout the time horizon of the following day.

The main idea is to see how the cost of rebalancing operations and the number of lost demand differ between the two cases, and thereby **evaluate the demand forecasting** by analyzing the trade-off between the two scenarios.

#### Previous work

#### Notation

Set V	the set of stations, $V = \{0,, N\}$ , where $\{0\}$ is the depot
Paramete	ers
Ν	the number of stations
т	number of relocation vehicles available
Q	capacity of a relocation vehicle
qCount	number of stations to be visited
c <sub>ii</sub>	length of the shortest path between <i>i</i> and <i>j</i> , $\forall i, j \in V$
q <sub>i</sub>	the difference between the number of bikes at station $i$ at the end of the previous day and the number of bikes desired at the beginning of the next day, $\forall i \in V$

#### **Decision variables**

- $x_{ij}$  1 if arc (i,j) is used by a relocation vehicle, 0 otherwise,  $i,j \in V$
- $\theta_i$  the load of a vehicle after it leaves node  $i, i \in V$
- $u_i$  auxiliary decision variable for the MTZ constraints,  $i \in V$

(日) (周) (日) (日) (日) (日) (000)

## Decision center - Modified model (Dell'Amico et al., 2013)

(F1M)	min $\sum_{i \in V} \sum_{i \in V} c_{ij} \times_{ij}$		(1)
	s.to $\sum_{i \in V} x_{ij} = 1$	$\forall j \in V \setminus \{0\}$	(2)
	$\sum_{i \in V} x_{ji} = 1$	$\forall j \in V \setminus \{0\}$	(3)
	$\sum_{j \in V} x_{0j} \le m$		(4)
	$\sum_{j \in V \setminus \{0\}} x_{0j} = \sum_{j \in V \setminus \{0\}} x_{j0}$		(5)
	$u_i - u_j + N * x_{ij} \le N - 1$	$\forall i, j \in V \setminus \{0\}$	(6)
	$1 \le u_i \le N - qCount$	$\forall i \in V$	(7)
	$\min\{Q, Q+q_j\} \ge \theta_j \ge \max\{0, q_j\}$	$\forall j \in V$	(8)
	$\theta_j - \theta_i + M(1 - x_{ij}) \ge q_j$	$\forall i \in V, j \in V \setminus \{0\}$	(9)
	$\theta_i - \theta_j + M(1 - x_{ij}) \ge q_j$	$\forall i \in V \setminus \{0\}, j \in V$	(10)
	$x_{ij} + \sum_{h \in S(i,j)} x_{jh} \le 1$	$\forall i,j \in V \setminus \{0\}, h \in S(i,j)$	(11)
	$\sum_{h \in S(i,j)} x_{hi} + x_{ij} \le 1$	$\forall i, j \in V \setminus \{0\}, h \in S(i, j)$	(12)
	$\theta_0 = 0$		(13)
	× <sub><i>ii</i></sub> = 0	$\forall i \in V$	(14)
	$x_{ij} \in \{0, 1\}$	$\forall i, j \in V$	(15)

B A B A B B B A A A

#### Clustering

## Performance measures

The performance measures are:

- (P1) the total in-cluster Manhattan distance,
- (P2) the deviation of the total in-cluster demand from zero, and
- (P3) the deviation of number of stations per cluster from the average number of stations per cluster.

## Clustering methods

We look into the following approaches:

- (C1): Agglomerative hierarchical clustering (AHC) with Ward linkage and proximity of stations as a similarity matrix
  - considers (P1)
- (C2): AHC with Ward linkage and number of trips between stations as a similarity matrix adapted from Lahoorpoor et al. (2019)
  - considers (P2)
- (C3): A mixed-integer non linear program
  - considers all performance measures
- (C4): A mixed-integer linear program
  - considers all performance measures

A = A = A = A = A = A

## Clustering methods - Notation

Parameters	
N	number of stations $(i, j \in \{1,, N\})$
С	number of clusters $(c \in \{1,, C\})$
d <sub>ii</sub>	the distance from station <i>i</i> to station <i>j</i> , $i, j \in N$
qi	the demand at each station, $i \in N$
α, β, γ	weight of $1^{st}$ , $2^{nd}$ and $3^{rd}$ objective function, respectively

#### Decision variable

 $s_{ic}$  1 if station *i* is assigned to cluster *c*, 0 otherwise,  $i \in N, c \in C$ 

#### Auxiliary decision variables

$devSN_c^+$ , $devSN_c^-$	the positive and negative deviation of number of stations in cluster $\boldsymbol{c}$
	from the average number of stations per cluster, $c \in C$ , respectively
$devD_c^+$ , $devD_c^-$	the positive and negative deviation of total demand from 0 in cluster
	$c, c \in C$ , respectively
inClusterDist <sub>c</sub>	the total Manhattan distance between each pair of stations in
	cluster $c, c \in C$
m <sub>ijc</sub>	1 if both $i$ and $j$ are in cluster $c$ , 0 otherwise, $i, j \in N, c \in C$

- Different clustering methods are assessed.
- AHC using proximity results in geographically collective clusters, but not zero demand deviation.

- Different clustering methods are assessed.
- AHC using proximity results in geographically collective clusters, but not zero demand deviation.
- AHC using number of trips brings about uneven distribution in number of stations.

- Different clustering methods are assessed.
- AHC using proximity results in geographically collective clusters, but not zero demand deviation.
- AHC using number of trips brings about uneven distribution in number of stations.
- (C4) overcomes this yet the areas spanned by each cluster tend to overlap some other clusters.

#### Future work

The future work includes

• A heuristic approach for multi-objective station clustering

EL OQO

#### Future work

The future work includes

- A heuristic approach for multi-objective station clustering
- Testing the approaches for many days to achieve statistical significance

ELE NOR

#### Future work

The future work includes

- A heuristic approach for multi-objective station clustering
- Testing the approaches for many days to achieve statistical significance
- The consideration of different data sets to derive conclusions about the relation between the city and demand structure
